Turning raw drive test data into actionable information

The new R&S®ROMES network problem analyzer software analyzes the large volumes of data captured in drive tests and breaks it down into relevant problem spots to help operators identify and clearly document weak points in mobile radio networks.

Gaining and maintaining a clear picture

It is a problem that mobile network operators know all too well: Drive tests generate vast quantities of data that need to be analyzed to identify weak points and gaps in network coverage. Manually analyzing data on this scale can be a laborious process — one that calls for special tools. For R&S®ROMES users, though, life is a whole lot easier, because the drive test software provides a useful array of tools designed to sequentially analyze individual measurements.

With the R&S®ROMES network problem analyzer (NPA) software, things are simpler still. This new tool can automatically evaluate mass test data and even entire drive test campaigns, either on a computer in the vehicle during an actual drive, or later, back in the office. Resorting to manual evaluation is only necessary in rare instances.

The software consists of a core analysis engine (which processes the test data from R&S®ROMES and dispatches it to a number of analysis plug-ins) and a user interface that displays the results in a clearly organized form.

The NPA uses dedicated analysis plug-ins for each of the tasks involved in post-processing the data. This modern architecture means that the software can be expanded quickly and easily to handle new or highly specialized tasks — by creating special analysis plug-ins (e.g. to identify uplink interference or to support new standards like LTE) or by implementing new views in the user interface to enhance the presentation of results. The optional software development kit (SDK) is also simple to use, enabling even users with a limited knowledge of programming to create their own plug-ins for any kind of drive test data processing.

FIG 1 A section of the page displayed when the R&S®ROMES NPA starts: It explains the basic workflow to help users familiarize themselves with the software quickly.
Easy-to-use interface …

The R&S®ROMES network problem analyzer software has a user-friendly browser-like interface designed to guide network optimizers and field engineers easily through the workflow. The start page contains all of the main functions and explains how these work together (FIG 1). It also includes links that display detailed views. This makes learning to use the software a simple process and enables users to produce usable results exceptionally fast. The results are displayed as problem lists, as tables of transactions, and as pie and bar charts of statistics (FIG 2).

Users can run the R&S®ROMES drive test software directly from any item in the problem lists. The software presents a problem area as a combination of time and location information, ready for deeper analysis. Due to this drill-down ability, which is performed automatically via a menu entry, it is not necessary to replay the test file at the desired point. This significantly accelerates file loading, especially with large files (FIGs 4 and 5). Users can increase and reduce the content of individual pages easily using drag-and-drop. For instance, they can drag additional results into the analysis view and extend tables and charts by inserting more data.

The basic version of the NPA provides comprehensive analysis functionality for voice calls in GSM/WCDMA networks. Depending on the outcome of voice call analysis, the software can run various problem detectors — to examine handover procedures, check coverage and interference, and identify network and mobile handset malfunctions, for example. This produces a catalog of problem spots, plus a prioritized list of causes identified for each problem spot (FIG 3).
FIG 4 A simple mouse click is all it takes to drill down from a problem spot into a detailed R&S®ROMES analysis.

FIG 5 R&S®ROMES synchronizes instantly with the NPA.
Other analysis modules can extract ETSI key performance indicators (KPIs) identified by R&S®ROMES and condition them so that they can be grouped and combined according to a variety of criteria. And if data throughput problems and their causes need to be identified, data transactions over HSDPA and HSUPA can be analyzed separately. The software assigns identified causes to different categories so that users can see which element in the network is causing a specific throughput problem.

In contrast to the analysis modules described above, the generic signal processor in the NPA enables the modules available in R&S®ROMES to be combined with mathematical and logical operators to create complex test data processors. These can either compile new problem lists or, alternatively, generate statistics from the signal processing results (FIG 6). This means that, in principle, there are no limits on how data acquired in drive tests can be post-processed.

Summary and future developments

The R&S®ROMES NPA greatly simplifies working with large volumes of drive test data. Its ability to access numerous powerful tools in the R&S®ROMES drive test software leverages capabilities in order to create a feature-rich solution that is greater than the sum of its parts. This new and powerful tool from Rohde&Schwarz delivers advanced post-processing functionalities that complement R&S®ROMES and R&S®ROMES2GO* to create a comprehensive drive test portfolio.

Additional analysis modules are currently being developed. These include a module for problem analysis during LTE network setup and an IP analyzer for failed data transactions that can identify where precisely a problem has occurred during call setup or data transmission, along with possible causes.

Likewise in the pipeline are new visualizations for the user interface, additional filtering options, and user-configurable views. The software will also include print-ready views to enable users to produce reports based on R&S®ROMES data and will allow analysis results to be stored in a database to enable even larger volumes of drive test data to be managed and evaluated efficiently.
